SYNERGISTIC COMBINATION FOR TREATMENT OF VIRAL-MEDIATED DISEASES

Field of the Invention

This invention relates to the use of interferons as antiviral agents.

Background to the Invention

Human interferons (IFN) were originally prepared from human white blood cells, a by-product of blood banks, and from primary human fibroblasts in culture. The white cell product was called human leukocyte interferon or human alpha interferon and the human fibroblast interferon was called human β interferon. Subsequent to the cloning of interferons in $E.\ coli$, several subtypes of human interferons have been identified. There are at least 15 subtypes of alpha interferon (Henco K. et al., J. Mol Biol. 185, 227-260, 1985) and only one β interferon.

Cyclopentenyl cytosine (CPE-C) was a promising anti-tumor compound in clinical trial until two deaths were observed in the trial. Four of the eleven patients who received 4.7 mg/m² per hour of CPE-C experienced hypotension 24 to 48 hours after completion of the CPE-C infusion during their first, third and sixth cycles respectively. Two of the four hypotensive patients died with refractory hypotension. The trial was immediately stopped by the National Cancer Institute, USA. Hypotension was not seen in patients receiving ≤2.5 mg/m² per h CPE-C (Cancer Chemother. Pharmacol. 36, 513-523, 1995). The mean CPE-C steady-state plasma levels (Cpss) increased linearly from 0.4µM to 3.1µM at doses ranging from 1 to 5.9

Mycophenolic acid was first demonstrated by H. Florey in 1946 to inhibit bacteria, fungi and leukocytes. The prodrug mycophenolate mofetil is now an FDA-approved transplantation drug.

Summary f the Invention

We have now found that an interferon such as interferon $\alpha 2$, interferon $\alpha 8$ or interferon β can act synergistically with particular compounds to combat flavivirus

15

20

25

30

 $mg/m^2/h$.

5

and rhabdovirus infections. This synergistic antiviral effect means that lower concentrations of the small molecular weight chemicals such as CPE-C can be used together with interferons as antiflaviviral and antirhabdoviral agents and at concentrations below its anticipated side effects (hypotension) in man $(1.0 \,\mu\text{M}\ \text{or}\ \text{less})$.

Accordingly, the present invention provides a method of treating a host having a flavivirus or rhabdovirus infection, which method comprises the step of administering to the host in respective amounts which produce a synergistic antiflaviviral or synergistic antirhabdoviral effect:

- 10 (a) an interferon, and
 - (b) at least one compound selected from the group consisting of
 - 5-membered cyclic nucleosides having the formula (I):

$$R_1$$
 X
 H
 R_2
 R_3
 R_3
 (I)

wherein $\cap X \cap is = CH_1$, $-CH_2$ or $-O_1$, Nu is selected from the group consisting of purines, pyrimidines and five- or six-membered aglycones, R_2 and R_3 are independently selected from the group consisting of H, OH, O-acyl, O-aryl and O-silyl, and R_1 is as defined for R_2 and R_3 or is O-phosphate, and pharmaceutically acceptable metabolites, metabolite derivatives and salts thereof:

mycophenolic acid compounds having the formula (II)

30

15

20

25

30

wherein R_4 is $-OR_6$ or $-N(R_7)$ R_8 in which R_6 , R_7 and R_8 are independently selected from the group consisting of hydrogen and C_1 - C_6 alkyl, and R_5 is selected from the group consisting of hydrogen, phenyl and C_1 - C_6 alkyl unsubstituted or substituted by a five- or six-membered saturated or unsaturated heterocyclic ring, and

- 5 pharmaceutically acceptable salts thereof;
 - imidazole derivatives represented by formula (III):

$$\begin{array}{c}
N \\
N \\
R_9
\end{array}$$
 $C \equiv CR_{10}$
(III).

wherein R₉ is a hydrogen atom or

wherein R_{10} is a hydrogen atom, C_1 - C_6 alkyl, hydroxy(C_1 - C_6 alkyl) or phenyl, R_{11} and R_{13} are independently selected from hydrogen and OR_{12} , R_{12} is a hydrogen atom or a hydroxy protecting group and A is $CONH_2$ or CN, and pharmaceutically acceptable salts thereof;

aminoadamantanes having the formula (IV):

$$R_{15}$$
 R_{14}
 R_{17}
 R_{19}
 R_{19}

wherein each of R_{14} , R_{15} , R_{16} and R_{17} is independently selected from the group consisting of H, F and CH₃ and X is $N(R_{18})_2$, $CH_2CH_2N(R_{18})_2$ or $C(R_{19})_2N(R_{18})_2$ wherein each R_{18} and R_{19} is H, (C_1-C_6) alkyl, (C_6-C_{10}) aryl and

(C₇-C₁₈) aralkyl; and

2,4-diaminopyrimidines having the formula (V):

$$\begin{array}{c|c}
NH_2 \\
R_{20} \\
R_{21}
\end{array}$$
(V)

wherein R_{20} is phenyl substituted by one or more substituents selected from the group consisting of aralkyl, NO_2 , (C_1-C_6) alkylamino and halogen and R_{21} is H or C_1-C_6 alkyl; or R_{20} and R_{21} form, together with the 2,4-diaminopyrimidine ring to which they are attached, a quinazoline derivative of formula (V'):

$$\begin{array}{c|c}
NH_2 & R_{22} \\
\hline
 & C & COOR_{24} \\
\hline
 & C & NH - CH \\
\hline
 & (CH_2)_nCOOR_{24}
\end{array}$$

$$(V')$$

20

5

10

15

wherein Z is $-CH_2NR_{23}$ - or $-NR_{23}CH_2$ -; R_{22} , R_{23} and R_{24} are each, independently, H or C_1 - C_6 alkyl; and n is 1 or 2, and pharmaceutically acceptable salts thereof.

In formula (V) the aralkyl substituent is an aryl group linked via an alkylene chain of 1 to 6 carbon atoms. Aryl is typically phenyl or naphthyl. Preferred examples of aralkyl are benzyl and phenethyl. In formula (V') R₂₂ is preferably methyl or ethyl, especially ethyl, R₂₃ and R₂₄ are preferably H and n is preferably 1.

The present invention encompasses all optical isomers of the compound (b), in particular the D- and L-isomers of the nucleosides of formula (I) and of the quinazoline derivatives of formula (V').

20

rhabdovirus infections also forms part of the invention. The invention therefore further provides a method of treating a host having a flavivirus or rhabdovirus infection, which method comprises the step of administering to the host a therapeutically effective amount of an interferon $\alpha 8$ having a specific activity of from 0.3×10^9 to 3×10^9 IU per mg protein.

The invention additionally provides:

- use of an interferon in the manufacture of a medicament for use with at least one compound (b) as defined above in the treatment of a flavivirus or rhabdovirus infection;
- use of at least one compound (b) as defined above in the manufacture of a
 medicament for use with an interferon in the treatment of a flavivirus or
 rhabdovirus infection;
 - products containing an interferon and at least one compound (b) as defined above as a combined preparation for simultaneous, separate or sequential use in treating a flavivirus or rhabdovirus infection;
 - interferon α8 having a specific activity of from 0.3x10° to 3x10° IU per mg of protein for use in a method of treatment of the human or animal body by therapy;
 - use of interferon α8 having a specific activity of from 0.3x10° to 3x10° IU per mg of protein in the manufacture of a medicament for use in the treatment of a flavivirus or rhabdovirus infection; and
 - an anti-flavivirus or anti-rhabdovirus agent comprising interferon α8 having a specific activity of from 0.3x10° to 3x10° IU per mg of protein.

25 <u>Detailed Description of the Invention</u>

Interferons

The interferon for use in the present invention may be an interferon α , such as interferon α 2 or α 8, or interferon β . The term "interferon" includes fragments which have interferon activity and mutant forms of an interferon which retain interferon activity. For example, the sequence of an interferon α or β may have been modified to enhance activity or stability as reported in US-A-5582824, US-A-5593667 or US-

15

20 -

A-5594107.

The interferon may have been purified from natural sources or may be a recombinant interferon. The species of interferon is generally the same as the host species to which the interferon is administered. The invention is particularly applicable to the treatment of flavivirus infections in humans. Preferably therefore a human interferon such as human interferon $\alpha 2$ or $\alpha 8$ or human interferon β is used.

The interferon α8, particularly the human interferon α8, typically has a specific activity of more than 0.6x10⁹, generally from 0.6x10⁹ to 1.5x10⁹ and preferably from 0.8x10⁹ to 1.5x10⁹, IU per mg protein. The human interferon β typically has a specific activity of from 4x10⁸ to 8x10⁸, preferably from 4.8x10⁸ to 6.4x10⁸, IU per mg protein. Interferon α and interferon β specific activities are determined according to reference standards Gb-23-902-530 and Gb-23-902-531 respectively. Specific activity is determined according to a modification of the method of Armstrong, Applied Microbiology 21, 723, 1971, in which 0.2 μg/ml of actinomycin D is included in the viral challenge and the viral induced cytopathic effect (CPE) is read directly from the primary human fibroblasts. Alternatively, specific activity is determined according to the method of Armstrong using WISH cells as assay cells and Encephalomyocarditis virus as challenge virus and the viral induced CPE is read directly.

The interferon such as the interferon $\alpha 2$ or $\alpha 8$ or the interferon β is preferably obtainable by the methodology of WO 96/30531. The interferon is thus obtainable by a process comprising culturing mammalian cells transfected with a nucleic acid vector comprising:

- (i) a coding sequence which encodes the interferon and which is operably linked
 to a promoter capable of directing expression of the coding sequence in mammalian cells in the presence of a heavy metal ion;
 - (ii) a first selectable marker sequence which comprises a metallothionein gene and which is operably linked to a promoter capable of directing expression of the metallothionein gene in the cells in the presence of a heavy metal ion; and
- 30 (iii) a second selectable marker sequence which comprises a *neo* gene and which is operably linked to a promoter capable of directing expression of the *neo*

15

20

25

gene in the cells;

unless conditions that allow expression of the coding sequence, and recovering the interferon thus produced.

The transfected mammalian cells may be cells of a human or animal cell line.

They may be BHK, COS, CHO Lec2, L CL3, Vero, human fibroblastoid such as

C1O, HeLa, or human lymphoblastoid cells or cells of a human tumour cell line.

Preferably, however, the cells are CHO cells, particularly wild-type CHO cells.

Desirably, transfected cells will have all or part of such a vector integrated into their genomes. Such cells are preferred because they give stable expression of the coding sequence contained in the vector. Preferably, one or more copies of the entire vector will be integrated, with cells having multiple integrated copies of the vector, for example from 20 to 100 copies or more, being particularly preferred because these cells give a high stable level of expression of the coding sequence contained in the vector.

However, cells having less than complete sections of the vectors integrated into their genomes can be employed if they are functionally equivalent to cells having the entire vector integrated into their genomes, in the sense that the integrated sections of the vector enable the cell to express the coding sequence and to be selected for by the use of heavy metals. Thus, cells exhibiting partial integration of a vector may be employed if the integrated element or elements include the coding sequence operably linked to its associated promoter and the metallothionein marker sequence operably linked to its associated promoter.

Any promoter capable of enhancing expression in a mammalian cell in the presence of a heavy metal ion such as Cd²⁺, Cu²⁺ and Zn²⁺ may be operably linked to the interferon coding sequence. A suitable promoter is a metallothionein gene promoter. The mouse metallothionein gene I (mMT1) promoter is preferred.

Suitable promoter/enhancer combinations for the coding sequence include the mMT1 promoter flanked upstream with a mouse sarcoma virus (MSV) enhancer (MSV-mMT1) and a Rous sarcoma virus (RSV) enhancer upstream of a mouse mammary tumour virus (MMTV) promoter. MSV-mMT1 is preferred.

As far as the first selectable marker sequence is concerned, any promoter

15

20

capable of enhancing expression in a mammalian cell in the presence of a heavy metal ion such as Cd²⁺, Cu²⁺ and Zn²⁺ may be operably linked to the metallothionein gene such as a human metallothionein gene. Preferably, the marker sequence gene is a human metallothionein gene, such as the human metallothionein gene IIA, which has its own promoter.

The second selectable marker sequence is a *neo* gene. More than one type of this gene exists in nature: any specific *neo* gene can be used in a vector of the invention. One preferred *neo* gene is the *E.coli neo* gene.

The promoter for the *neo* gene is capable of directing expression of the gene in a mammalian cell. Suitable promoters are the cytomegalovirus (CMV) early promoter, the SV40 promoter, the mouse mammary tumour virus promoter, the human elongation factor 1 α -P promoter (EF-1 α -P), the SR α promoter and a metallothionein gene promoter such as mMT1. The promoter may also be capable of expressing the *neo* gene in bacteria such as *E.coli* in which a vector may be constructed.

The interferon coding sequence (i) and the marker sequences (ii) and (iii) are thus each operably linked to a promoter capable of directing expression of the relevant sequence. The term "operably linked" refers to a juxtaposition wherein the promoter and the coding/marker sequence are in a relationship permitting the coding/marker sequence to be expressed under the control of the promoter. Thus, there may be elements such as 5' non-coding sequence between the promoter and coding/marker sequence. Such sequences can be included in the construct if they enhance or do not impair the correct control of the coding/marker sequence by the promoter.

Typically, the vector is a plasmid. Each of the sequences (i) to (iii) will typically be associated with other elements that control their expression. In relation to each sequence, the following elements are generally present, usually in a 5' to 3' arrangement: a promoter for directing expression of the sequence and optionally a regulator of the promoter, a translational start codon, the coding/marker sequence, a polyadenylation signal and a transcriptional terminator.

15

20

25

Further, the vector typically comprises one or more origins of replication, for example a bacterial origin of replication, such as the pBR322 origin, that allows replication in bacterial cells. Alternatively or additionally, one or more eukaryotic origins of replication may be included in the vector so that replication is possible in, for example yeast cells and/or mammalian cells.

The vector may also comprise one or more introns or other non-coding sequences 3' or 5' to the coding sequence or to one or more of the marker sequences. Such non-coding sequences may be derived from any organism, or may be synthetic in nature. Thus, they may have any sequence. Such sequences may be included if they enhance or do not impair correct expression of the coding sequence or marker sequences.

The transfected cells are typically cultured in the presence of a heavy metal ion selected from Cd^{2+} , Cu^{2+} and Zn^{2+} , particularly in an amount which is not toxic to the cells. That can lead to higher expression of the desired interferon. The concentration of the heavy metal ion in the culture medium is typically from 100 to 200 μ M. Cells may therefore be cultured in the presence of from 100 to 200 μ M of a heavy metal ion selected from Cd^{2+} , Cu^{2+} and Zn^{2+} , for example from 130 to 170 μ M of the heavy metal ion. A useful concentration is about 150 μ M, particularly when the heavy metal ion is Zn^{2+} .

The interferon that is produced may be recovered by any suitable means and the method of recovery may vary depending on, for example, the type of cells employed and the culture conditions that have been used. Desirably, the interferon produced will be purified after recovery. Substantially pure interferon can thus be obtained.

The human β -interferon provided by WO 96/30531 has a high degree of sialylation. Like natural human β -interferon produced by primary diploid human fibroblasts, it is well glycosylated. However, it has a higher bioavailability than the natural β -interferon or recombinant β -interferon produced in *E.coli* (betaseron).

The higher bioavailability of the β-interferon can be characterised. When 1.5

x 10⁶ IU of the interferon is injected subcutaneously into the back of a rabbit of about 2 kg: (a) ≥ 128 IU/ml of the interferon is detectable in the serum of the rabbit after 1

hour, and/or (b) \geq 64 IU/ml of the interferon is detectable in the serum of the rabbit after 5 hours.

The maximum level of interferon is typically observed after 1 hour. According to (a), therefore, 128 to 256 IU/ml such as 140 to 190 IU/ml of the interferon may be detectable in the rabbit serum after 1 hour. After 5 hours according to (b), ≥ 70 IU/ml such as ≥ 80 IU/ml of the interferon may be detectable in the rabbit serum. Typically according to (b), an amount of interferon in the range of 64 to 128 IU/ml such as 80 to 110 IU/ml can be detected.

Additionally or alternatively, the human interferon β can be characterised by its specific activity. It can have a specific activity from 4.8×10^8 to 6.4×10^8 IU per mg equivalent of bovine serum albumin protein, as noted above. The specific activity may be from 5×10^8 to 6×10^8 , for example from 5.2×10^8 to 5.8×10^8 such as from 5.3×10^8 to 5.5×10^8 , IU per mg equivalent of bovine serum albumin protein.

The human interferon β may also be characterised by one or more of the following properties:

- 1. The interferon β typically has an apparent molecular weight of 26,300 as determined by 15% sodium dodecyl sulphate-polyacrylamide gel electrophoresis (SDS-PAGE).
- When injected as a neat intravenous bolus into a rabbit, the half life of the interferon is typically in the range of from 12 to 15 min such as about 13½ min. The bolus is injected into the rabbit ear vein and blood samples are withdrawn from the rabbit ear artery. Rabbit serum is assayed for the antiviral activity of the interferon according to the modification of the method of Armstrong (1971).
 - 3. The antiviral activity of the interferon in a human hepatoblastoma cell line (HepG2) is at least equal to and, typically, about 1.5 times the activity of natural interferon β from primary diploid human fibroblast cells. The interferon is also about 2.2 times more effective than betaseron in protecting Hep2 cells against a viral challenge. Antiviral activity is again determined according to the modified method of Armstrong (1971). Actinomycin D was

15

omitted in the antiviral determination in HepG2 cells.

The oligosaccharides associated with the interferon β of the invention may also characterise the interferon β . The interferon β carries oligosaccharides which can be characterised by one or more of the following features:

- Neutral (no acidic substituents): 5 to 15%, preferably about 10% or lower.

 Acidic: 95 to 85%, preferably about 90% or higher.
 - 2. The total desialylated oligosaccharide pool is heterogeneous with at least six distinct structural components present in the pool.
 - 3. Matrix-Assisted Laser Desorption Ionisation Time of Flight (MALDI-TOF)
 mass spectrometry and high resolution gel permeation chromatography data
 are summarised as follows:

| Mass detected | Composition | Calculated Mass | gu equivalent |
|---------------|---------------------------------------|-----------------|---------------|
| 1786.2 | 5Hex, 4HexNAc, 1 2AB, Na | 1782 | 11.1 |
| 1929.9 | 5Hex,1dHex, 4HexNAc, 1 2AB, Na | 1928 | 12.2 |
| 2295.5 | 6Hex, 1dHex, 5HexNAc 1 2AB, Na | 2293 | 14.5 |
| 2660.1 | 7Hex, 1dHex, 6HexNAc 1 2AB, Na | 2658 | 17.6 |
| 3019.1 | 8Hex, 1dHex, 7HexNAc, 1 2AB, Na | 3023 | 20.7 |

20

25

The carbohydrate moiety of the human interferon β of WO 96/30531 consists of bi-, tri- and tetra-antennary complex type N-linked oligosaccharides. These oligosaccharides contain repeating lactosamine(s). About 20 to 50%, for example 20 to 30%, 30 to 40% or 35 to 50%, of the oligosaccharides are bi-antennary

10

-15

20

25

30

oligosaccharides. About 30 to 65%, for example from 40 to 60% or 50 to 60%, of the oligosaccharides are tri-antennary oligosaccharides. About 2 to 15%, for example from 2 to 8%, 4 to 10% or 5 to 15%, of the oligosaccharides are tetra-antennary oligosaccharides. Percentages are calculated by weight of total analysable oligosaccharide content.

Compounds (b)

The compounds (b) are capable of inhibiting particular enzymes. Amongst the 5-membered cyclic nucleosides of formula (I), some of those in which $^{\sim}X^{\sim}$ is -O-, such as pyrazofurin and 6-azauridine, are inhibitors of orotidylate decarboxylase whilst tiazofurin and selenofurin are inhibitors of inositol monophosphate dehydrogenase (IMPH). Compounds of formula (I) in which $^{\sim}X^{\sim}$ is =CH- are typically inhibitors of cytosine triphosphate (CTP) synthetase and S-adenosylhomocysteine hydrolase.

The mycophenolic acid compounds of formula (II) and the imidazole derivatives of formula (III) are typically inhibitors of inosine monophosphate (IMP) dehydrogenase. The aminoadamantanes of formula (IV) inhibit the uncoating of influenza viruses. The 2,4-diaminopyrimidines of formula (V) and the quinazoline derivatives of formula (V') are inhibitors of dihydrofolate reductase.

In one embodiment the 5-membered cyclic nucleosides of formula (I) are cyclopentenyl carbocyclic nucleosides in which $^{\sim}X^{\sim}$ is =CH-. These have the following structure (I'):

$$R_1$$
 N_u R_2 R_3 N_u

wherein R₁, R₂, R₃ and Nu are as defined above for formula (I).

Preferred 5-membered cyclic nucleosides of formula (I) and cyclopentenyl carbocyclic nucleosides of formula (I') are compounds in which Nu denotes one of

30

the following groups (i) to (viii):

wherein R₂₅ is Cl or NH₂ and R₂₆ is H, CH₃, CF₃, F, Cl, Br or I.

When one or more of R₁, R₂ and R₃ is O-acyl in formula (I) or (I'), the acyl group is preferably a group having the formula R₂₇-CO- in which R₂₇ is C₁-C₆ alkyl such as C₁-C₄ alkyl, for example methyl or ethyl. The O-aryl group is generally a O-25 (C₆-C₁₀) aryl group such as O-phenyl or O-benzyl. R₂ and R₃ may together denote a ketal group such as

The 5-membered cyclic nucleosides of formula (I) are known compounds and

may be synthesised by published procedures or by analogy with published procedures. For instance the synthesis of carbocyclic adenosine [(±)-aristeromycin] is described by Shealy et al in J. Am Chem. Soc. 1966, 88, 3885 and in J. Am. Chem. Soc. 1969, 91, 3075. The enantioselective synthesis of (-) aristeromycin and (-)5 neplanocin A is described by Arita et al in J.Am. Chem. Soc. (1983), 105 (12), 4049-4055.

The synthesis of pyrazofurin is described by Petrie et al in J. Med. Chem

1986, 29, 268-278. The synthesis of 6-azauridine is described by Cristescu in Rev. Roum. Chim (1968), 13(3), 365-9. The synthesis of tiazofurin (2-β-D-ribofuranosylthiazole-4-carboxamide) and selenofurin (2-β-D-ribofuranosylselenazole-4-carboxamide) is described by Hennen *et al* in J. Org. Chem (1985) 5O(10), 1741-1746. The synthesis of suitable cyclopentenyl carbocyclic nucleosides of formula (I') is described in US-A-4975434, the contents of which are

The substitution patterns of preferred compounds of formula (I) are shown in Table 1 below. A particularly preferred compound is cyclopentenyl cytosine (CPE-C).

incorporated herein by reference. Specific nucleosides are listed in that patent.

As used herein the term "metabolite" refers to a compound for which a compound of formula (I) is a prodrug. For instance, tiazofurin and selenofurin are prodrugs for thiazolamide adenine dinucleotide (TAD) and selenazolamide adenine dinucleotide (SAD), respectively. In each case the metabolite, rather than the prodrug, is the active moiety. Examples of derivatives (or analogues) of these particular metabolites, which are also encompassed within the present invention, include beta-methylene TAD and beta-methylene SAD. These compounds are published in the literature.

The mycophenolic acid compounds of formula (II) include compounds in which R_4 is hydroxy or NH_2 . When one or more of R_5 , R_6 , R_7 and R_8 is a C_1 - C_6 alkyl group, preferably it is a C_1 - C_4 alkyl group such as methyl or ethyl. The five- or six-membered saturated or unsaturated heterocyclic ring generally contains one, two or three N-atoms and optionally an O- and/or S-atom. Suitable such rings include pyridino, piperidino, pyrrolo, pyrrolidono and morpholino rings. A N-morpholino ring may thus be present.

Mycophenolic acid compounds for use in the invention include mycophenolic acid, mycophenolate mofetil which is the morpholinoethyl ester of mycophenolic acid, and the individual mycophenolic acid derivatives described in US-A-5380879. The contents of US-A-5380879 are incorporated herein by reference.

15

20

Suitable imidazole derivatives of formula (III) are compounds wherein R_{10} is hydrogen, C_1 - C_4 alkyl such as methyl or ethyl, hydroxy(C_1 - C_4 alkyl) in which the alkyl group may be methyl or ethyl, or phenyl. R_{12} may be hydrogen or any appropriate protecting group such as an acyl, alkyloxymethyl, substituted ethyl, aralkyl, pyranyl, silyl, acetal or ketal group. Typically, R_{11} and/or R_{13} is H or OH.

Imidazole derivatives of formula (III) are described in US-A-5126361, the contents of which are incorporated herein by reference. A particularly preferred imidazole derivative is 5-ethynyl-1- β -D-ribofuranosyl-imidazole-4-carboxamide (EICAR). EICAR is a compound of formula (III) in which A is CONH₂, R₉ is D-ribose and R₁₀ is hydrogen.

Aminoadamantanes of formula (IV) are described in US-A-5599998, the contents of which are incorporated herein by reference. In formula (IV), R_{18} and R_{19} may each independently denote hydrogen, C_1 - C_4 alkyl such as methyl or ethyl, phenyl or benzyl. Suitable compounds include 1-aminoadamantane ("amantidine"), α -methyl-1-adamantylmethylamine ("rimantadine") and 1-amino-3,5-dimethyladamantane ("momantine").

The synthesis of 2,4-diaminopyrimidines of formula (V) is described by D. J. Brown in the chapter "Pyrimidines and their Benzo Derivatives" in Comprehensive Heterocyclic Chemistry, Vol. 3, part 2B, A. Boulton and A. McKillop (Eds), 1983, Pergamon, Oxford, page 151, the contents of which are incorporated herein by reference. The substitution patterns of preferred compounds of formula (V) are shown in Table 2 below:

Table 2: Substitution patterns within formula (V)

The quinazoline derivatives of formula (V') may be synthesised as described by Hynes *et al* in J.Med. Chem., 1977, Vol 20, No. 4, 588-591 or by analogy with the methods described there. A preferred quinazoline derivative of formula (V') is the compound wherein R₂₂ is C₂H₅, R₂₃ and R₂₄ are both H and n is 1. This is known as NSC 184692.

Pharmaceutically acceptable salts, particularly pharmaceutically acceptable acid addition salts, of any of the compounds of formula (I) to (IV) may be used. Salts with physiologically acceptable inorganic or organic acids may be employed, for example the hydrochloride salt.

15 Therapeutic uses

The interferons and compounds (b) are used together to treat flavivirus and rhabdovirus infections, particularly in humans. The infection may be acute or chronic. The flavivirus may be yellow fever virus, kunjin virus, dengue virus, hepatitis C virus, or an encephalitis virus such as St. Louis encephalitis virus,

20 Japanese encephalitis virus, Murray valley encephalitis virus and tick-borne

15

encephalitis virus. The rhabdovirus may be vesicular stomatitis virus (VSV) or rabies virus.

The interferon and at least one compound (b) are administered to a subject to be treated in sufficient amounts to produce a synergistic antiflaviviral or synergistic antirhabdoviral effect. The condition of the subject can thus be improved. The infection may be cleared from the subject entirely. Relative to monotherapy, lower doses of the interferon and of the compound(s) (b) can be used, which results in a cost-saving and a reduction or elimination of side effects that might occur at higher doses.

Separate formulations of the interferon on the one hand and of the compound(s) (b) on the other hand will generally be given to a patient. A single formulation containing both components can be administered if the interferon and compound(s) (b) are stable in each other's presence and do not otherwise interfere with each other.

The interferon may be administered to humans in various manners such as orally, intravenously, intramuscularly, intraperitoneally, intranasally, intradermally, topically and subcutaneously. The particular mode of administration and dosage regimen will be selected by the attending physician taking into account a number of factors including the age, weight and condition of the patient, the nature of the viral infection, the compound(s) (b) with which it is being administered and the need to obtain a synergistic effect.

The pharmaceutical compositions that contain the interferon as an active principal will normally be formulated with an appropriate pharmaceutically acceptable carrier or diluent depending upon the particular mode of administration being used. For instance, parenteral formulations are usually injectable fluids that use pharmaceutically and physiologically acceptable fluids such as physiological saline, balanced salt solutions, or the like as a vehicle. Oral formulations, on the other hand, may be solids, e.g. tablets or capsules, or liquid solutions or suspensions.

The interferon will usually be formulated as a unit dosage form that contains from 10⁴ to 10⁹, more usually 10⁶ to 10⁷, IU per dose. Typically from 3 x 10⁶ to 18 x 10⁶ IU of interferon is administered per day, particularly by injection such as

intravenously or subcutaneously. The dosage may be administered daily, for example for up to five or up to twenty weeks.

The compound(s) (b) can similarly be administered in a variety of dosage forms, for example orally such as in the form of tablets, capsules, sugar- or film-coated tablets, liquid solutions or suspensions, topically such as in the form of creams, ointments or gels, or parenterally, for example intramuscularly, intravenously or subcutaneously. They may therefore be given by injection or infusion.

The mode of administration and dosage regimen of the compound(s) (b) also depends on a variety of factors including the particular compound(s) (b) concerned, the age, weight and condition of the patient, the nature of the viral infection and the need to obtain a synergistic effect. Typically, however, the dosage adopted for each route of administration for humans, for example adult humans, is 0.001 to 10 mg/kg, most commonly in the range of 0.01 to 5 mg/kg, body weight. Such a dosage may be given, for example, daily. The dosage may be given orally or by bolus infusion, infusion over several hours and/or repeated administration.

The interferon and the compound(s) (b) may be given simultaneously.

Alternatively they may be given up to five days from each other, for example up to two days apart or up to one day apart or up to four hours apart. The relative timing of the administration of the interferon and the compound(s) (b) may be determined by monitoring their respective serum levels. The interferon may be given before the compound(s) (b) or vice versa. Two or three compound(s) (b) may be given, for example simultaneously or spaced apart timewise as above.

A suitable treatment regiment may be illustrated with reference to CPE-C. As noted previously, two patients treated with CPE-C died in a clinical trial as a result of hypotension. At dosages ≤2.5 mg/m²/h no hypotension was observed. Consequently, interferon α8 or interferon β must be used with CPE-C at dosages of CPE-C below which substantial hypotension occurs.

This may be achieved according to the invention by subcutaneous or intravenous injection of from 0.01 to 2.5 mg of CPE-C/m²/h and from 3 to 18, for example 3, 6, 12 or 18, x 10⁶ IU of interferon on day 1. The CPE-C may be injected simultaneously with the interferon. Alternatively, the interferon may be injected up

to 4 hours later, for example from 1 to 4 hours later. On days 2 and 3, 3 to $18x10^6$ IU of the interferon may be given to the patient. On day 4, the combination treatment of CPE-C and interferon can be repeated. This regimen may be repeated for several weeks, for example up to five or up to twenty weeks.

5

The following Examples illustrate the invention.

10 Example 1

Vero cells were grown to about 99% confluency in 96 microwells with minimum essential medium (MEM) containing 10% fetal calf serum. Growth medium was removed from the microwells and incubated with one of the following. The experiment was done in quadruplicates or duplicates:-

15

25

- (1) 100μl of interferon α8 containing either 6, 3, 0.6, 0.3, 0.06, or 0.03 IU of interferon (Reference to Gb 23-902-531, NIH standard, distributed by the Natl. Inst. Allergy and Infectious Diseases, NIH, USA) per ml of MEM containing 2.5 mg/ml human serum albumin.
- 20 (2) 100µl of interferon α2 containing either 6, 3, 0.6, 0.3, 0.06 or 0.03 IU of interferon (Reference to Gb-23-902-530 as well as Gb-23-902-531 standards) per ml of MEM containing 2.5 mg/ml human serum albumin.
 - (3) 100μl of interferon β containing 60, 30, 6, 3 or 0.6 IU of interferon (Reference to Gb23-902-531 standard) per ml of MEM containing 2.5 mg/ml human serum albumin.

After the addition of interferon to the Vero cells in the microwell, 100µl of a viral challenge consisting of 100 TCLD₅₀ yellow fever virus, kunjin virus or dengue virus was added immediately to each of the microwells. Different concentrations of test compound were included in the viral challenge as well. In the case where no test compound was used (i.e. the viral control), only 100µl of the viral challenge was

added to the wells in 100 µl of MEM containing 2.5 mg/ml human serum albumin.

The test compounds used were cyclopentenyl cytosine (CPE-C) from the National Cancer Institute, USA; mycophenolic acid from Sigma Chemicals; 5-ethynyl-1-β-D-ribofuranosylimidazole-4-carboxamide (EICAR); and amantadine hydrochloride.

In the control cells treated with test compound alone, 100 μl of MEM containing 2.5 mg/ml human serum albumin instead of interferon was added to the cells followed by an addition of another 100 μl of MEM/human serum albumin (2.5 mg/ml) containing test compound. In the case of CPE-C, the concentrations of CPE-10 C in MEM were 2 μM, 0.22 μM and 0.022 μM. The subsequent concentrations of CPE-C in the wells were therefore 1 μM, 0.11 μM and 0.011 μM.

The cells were examined for virus-induced cythopathic effects on day 5, day 8 and day 9 respectively for the antiviral activities of interferon or of test compound(s) or of interferon and test compound(s) protecting against a challenge virus of yellow fever, kunjin or dengue virus. The results of the enhancement of the antiviral effect of interferon by CPE-C is given in Table 3.

Table 3

- * 75-90% of the Vero cells were protected against a yellow fever virus challenge of 100 TCLD₅₀
- 10 ** 40-50% of the Vero cells were protected against a yellow fever virus challenge of 100 TCLD₅₀.
 - # none of the Vero cells were protected against a yellow fever virus challenge of 100 TCLD₅₀ at this concentration of CPE-C.
- Similar results in enhancement of the antiviral activity of interferon were observed when a viral challenge of 100 TCLD₅₀ of kunjin virus (0.11 μM of CPE-C enhanced interferon α8, interferon α2 and interferon β by 10-, 5- and 5-fold respectively) or dengue virus (0.11 μM of CPE-C enhanced interferon α8, interferon α2 and interferon β by 12-, 5- and 6-fold respectively) was used in place of yellow fever virus.

Similar experiments were repeated with mycophenolic acid, amantadine hydrochloride and EICAR. The concentration required to enhance the anti-viral activity of human interferon as is summarized in Table 4.

Table 4

| Human interferon | μM of test compounds # | | enhancen iviral acti | | |

| | | 9. | | | |

10

20

25

5

Indicates the concentration of test compound alone to protect Vero cells against a viral challenge by approximately 50%. In the case of mycophenolic acid, 2% fetal calf serum was used in place of human serum albumin.

15 Example 2

Monkey (Vero) or human (HuH7) cells were grown on 96 microwells as described in Example 1. When the cells were grown to 90-100% confluency with growth medium (MEM or DMEM) containing 5 or 10% fetal calf serum, the growth medium was removed from the microwells and the cells re-incubated with one of the following. The experiment was done in quadruplicates or duplicates:-

100 μl of human interferon α8, α2 or β interferon serially diluted from 30, 10, 3.3, 1.0, 0.33, 0.1, 0.033, 0.01, etc (Reference to Gb 23-902-531, NIH standard, distributed by the Natl. Inst. Allergy and Infectious Diseases, NIH, USA). In certain experiments using human cells, a serial 2-fold dilution of the interferon was used instead of the 30, 10, 3.3, 1.0, etc, dilution steps.

After adding the different concentrations of interferon to the cells in the microwells, 100 µl of a viral challenge (yellow fever, dengue, kunjin virus or VSV)

30 was immediately added to the microwells of cells previously treated with interferon and such that the viral challenge has a final TCLD₅₀ of 100. Different concentrations of test compounds were added in the viral challenge. In the case where no test

20

compound was used (viral control) 100 µl viral challenge was added to the wells in 100 µl of MEM containing 2.5 mg/ml human serum albumin. The interferon control cells were challenged with virus without test compound. The test compound controls were challenged with virus but no interferon. The test compounds used were cyclopentenyl cytosine (CPE-C) from the National Cancer Institute, USA; mycophenolic acid from Sigma Aldrich Inc.; 5-ethynyl-1-β-D-ribofuranosylimidazole-4-carboxamide (EICAR); amantadine hydrochloride; neplanocin A (provided by NCI, U.S.A.); 3-deazaneplanocin A (provided by NCI, USA); 3-deazauridine (Aldrich Chemical Co Inc.); NSC 382046, NSC 143095 and Artisteromycin (Sigma Aldrich Inc).

The cells were examined for virus-induced cytopathic effects on days 1, 2, 3, 4, 5, 6, 7 and 8, depending on the virus used for the antiviral activities of interferon or of test compound(s) or of interferon and test compound(s) protecting against a challenge virus of either yellow fever, dengue, kunjin virus or VSV. The results of the enhancement of the antiviral effect of the interferon used by each of the above test compounds are shown in the following Tables 5 to 22.

In the tables the IC_{50} values represent the concentration of each agent required to give a 50% inhibition of cell death following viral challenge. Where an IC_{50} value is shown as zero for one agent, that agent was not present. In those cases the IC_{50} given for the other agent is the ED_{50} of the latter alone.

CI in the tables represents the combination index. This is a parameter which reflects the presence or absence of synergism between two pharmacologically active agents. The calculation of the combination index is described by T.M. Brennan *et al* in Antiviral Research 1995, 173-187. The equation as used in the present

25 experiments was therefore

$$CI = \left(\frac{\text{concentration of drug (b)}}{\text{IC}_{50} \text{ of drug (b) alone}} \right) + \left(\frac{\text{concentration of IFN}}{\text{IC}_{50} \text{ of IFN alone}} \right)$$

The little of the test of the section with the section wi

is less than 1 they have a synergistic effect. If the CI is greater than 1 they have a mutually antagonistic effect. (M.C. Berenbaum in Pharmacol. Rev. 41, 93-141 (1989)).

Example 3

5

By following the experimental procedure described in Examples 1 and 2 the compound NSC 184692 was found to have an ED₅₀ against dengue virus of 120 pM in monkey Vero cells subjected to viral challenge by 100 TCLD₅₀ dengue virus. It was found that 100 pM of the compound enhanced the anti-viral effect of human 10 IFNβ 10-fold.
